Behavioral patterns

Conclusions

Structural Mappings

mpedance Mismatch

| Object-Oriented | Relational |
|-----------------|--------------------|
| Classes | Relation (table) |
| 0bject | Tuple (row) |
| Attribute | Attribute (column) |
| Identity | Primary Key |
| Reference | Foreign Key |
| Inheritance | N/A |
| Methods | ~ Stored Procedure |

Example of Domain Model

Person

-firstname : String

-lastname : String

-ssn: String

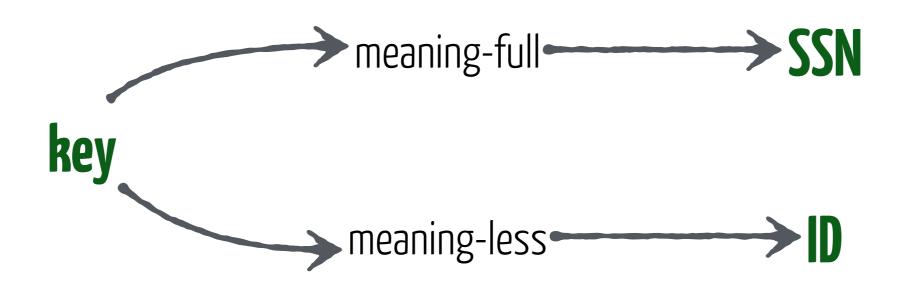

| first_name | last_name | SSN |
|------------|-----------|-------------|
| Sébastien | MOSSER | 16118325358 |
| ••• | | |

Problem: Domain Object Identity

```
Person p1 = new Person("X", "Y", "DDMMYYXXXXX")
Person p2 = new Person("X", "Y", "DDMMYYXXXXXX")
```

How to support persons **Uniqueness**?

Candidates for **Key** role

- Necessary condition:
 - Key must be unique
- Nice-to-have condition:
 - Key should be immutable
- Compound versus Simple

Pattern: Identity Field

Not visible at the business level Person -id: Long +firstname: String +lastname: String auto-generated +ssn: String GUID

When are 2 customers equals?

Problem: Representing associations

Artist -id : Long +name : String 1 Album -id : Long +title : String

artists

| id | name | |
|----|-------------|--|
| 1 | Linkin Park | |
| | ••• | |

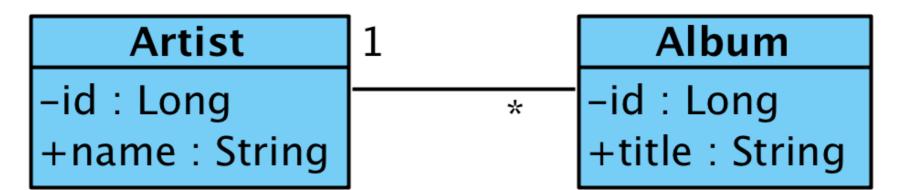

albums

| id | title |
|----|---------------------|
| 1 | A Thousand Suns |
| 2 | Minutes to Midnight |
| | ••• |

How to bind customers to orders?

Solution #1: Association Table [M-N]

artists

| id | name | |
|-----|-------------|--|
| 1 | Linkin Park | |
| ••• | | |

[PoEAA]

artists_to_albums

| artist_id | album_id |
|-----------|----------|
| 1 | 1 |
| 1 | 2 |
| ••• | |

albums

| id | title |
|-----|---------------------|
| 1 | A Thousand Suns |
| 2 | Minutes to Midnight |
| ••• | |

Solution #2: Foreign Key

[1-N]

| Artist | 1 | Album |
|----------------|---|-----------------|
| -id : Long | * | -id : Long |
| +name : String | | +title : String |

<u>artists</u>

| id | name | |
|-----|-------------|--|
| 1 | Linkin Park | |
| ••• | | |

albums

| id | title | artist_id |
|-----|---------------------|-----------|
| 1 | A Thousand Suns | 1 |
| 2 | Minutes to Midnight | 1 |
| ••• | | |

or $\begin{bmatrix} 1-N \end{bmatrix} \equiv \begin{bmatrix} M-N \end{bmatrix}$ when N=1

Solution #3: Relation Merge

[1-1]

Date

+day: Int

+month : Int +year : Int

[PoEAA]

birth

Artist

-id: Long

+name: String

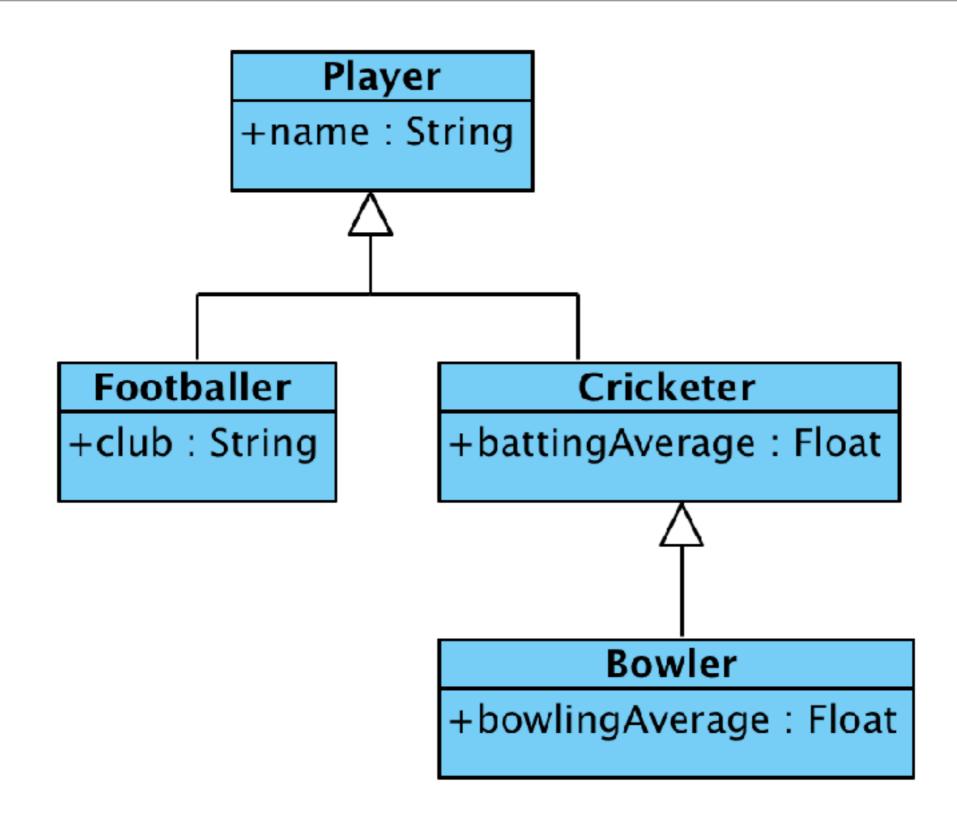

artists

| id | name | birth_day | birth_month | birth_year |
|-----|-------------|-----------|-------------|------------|
| 1 | Linkin Park | -1 | -1 | -1 |
| ••• | | | | |

or
$$[1-1] \equiv [1-N]$$
 when $N = 1$

or $[1-1] \equiv [M-N]$ when M = 1 and N = 1

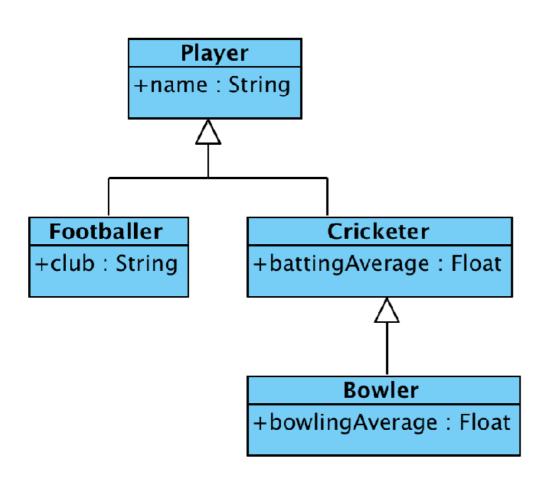

Problem: Implementing Inheritance

How to model multiple kind of customers?

Solution #1: Single-Table Inheritance

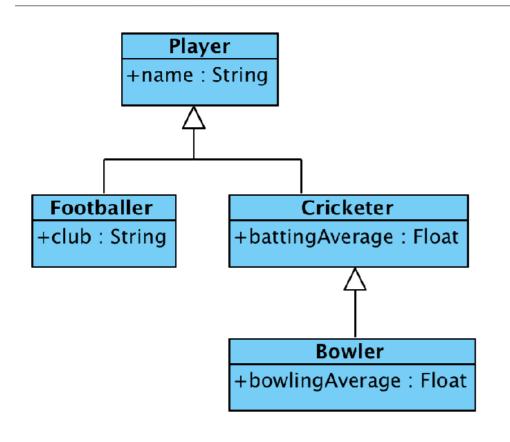

players

| name | club | batting_avg | bowling_avg | type |
|------|------|-------------|-------------|------|
| | | | | |

Solution #2: Class-Table Inheritance

players

| id | name | |
|----|------|--|
| 42 | ••• | |
| 74 | ••• | |
| 96 | ••• | |

footballers

| id | club | |
|----|------|--|
| 42 | ••• | |

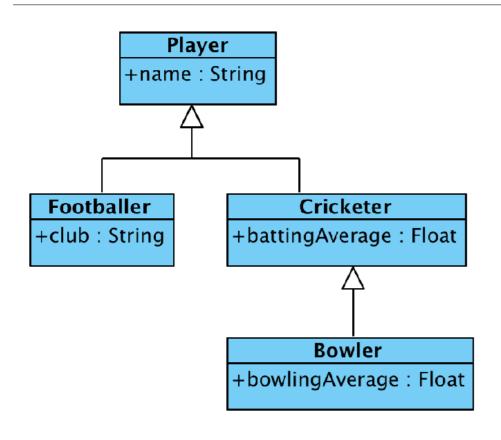

cricketers

| id | batting_avg |
|----|-------------|
| 74 | ••• |
| 96 | ••• |

bowlers

| id | bowling_avg |
|----|-------------|
| 96 | ••• |

Solution #3: Concrete-Table Inheritance

footballers

| id | name | club |
|----|------|------|
| 42 | ••• | ••• |

cricketers

| id | name | batting_avg |
|----|------|-------------|
| 74 | ••• | ••• |

bowlers

| . | name | batting_avg | batting_avg |
|----------|------|-------------|-------------|
| 96 | ••• | ••• | |

Architectural patterns

How one can interact with the persistent objects?

Table-Data Gateway

Person

-id : Long

+firstname : String

+lastname : String

+ssn: String

PersonGateway

+insert(id : Long, p : Person)

+update(p : Person)

+delete(p : Person)

+findByld(id : Long) : Person

+findByFirstName(s : String) : Person []

+findByLastName(s : String) : Person [

+findBySSN(s : String) : Person []

Decoupling Finder from Gateway

```
Person
      PersonGateway
                                           -id : Long
+insert(id : Long, p : Person)
                                           +firstname : String
+update(p : Person)
                                           +lastname: String
                             <<use>:
+delete(p : Person)
                                           +ssn: String
                               <<use>>
            PersonFinder
+findById(id : Long) : Person
+findByFirstName(s : String) : Person []
+findByLastName(s : String) : Person []
+findBySSN(s : String) : Person []
```

Active Record

```
PersonRecord
-id: Long
+firstname: String
+lastname : String
+ssn: String
+insert()
+update()
+delete()
+greetings(): String
```

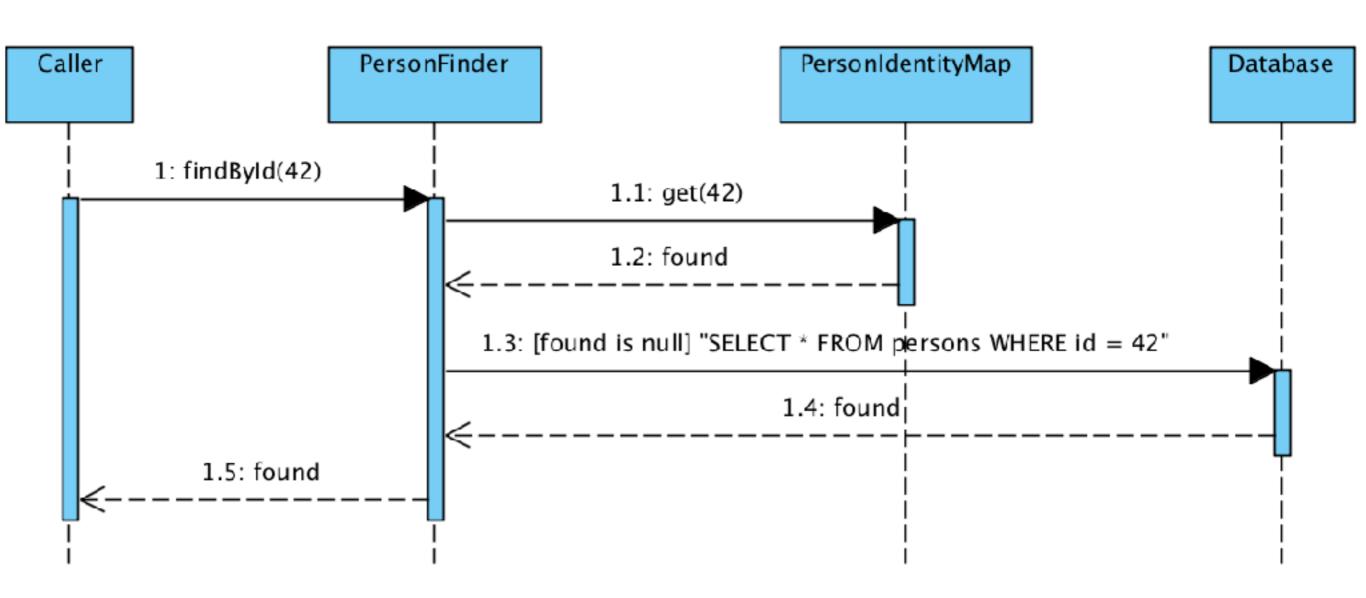

Behavioral patterns

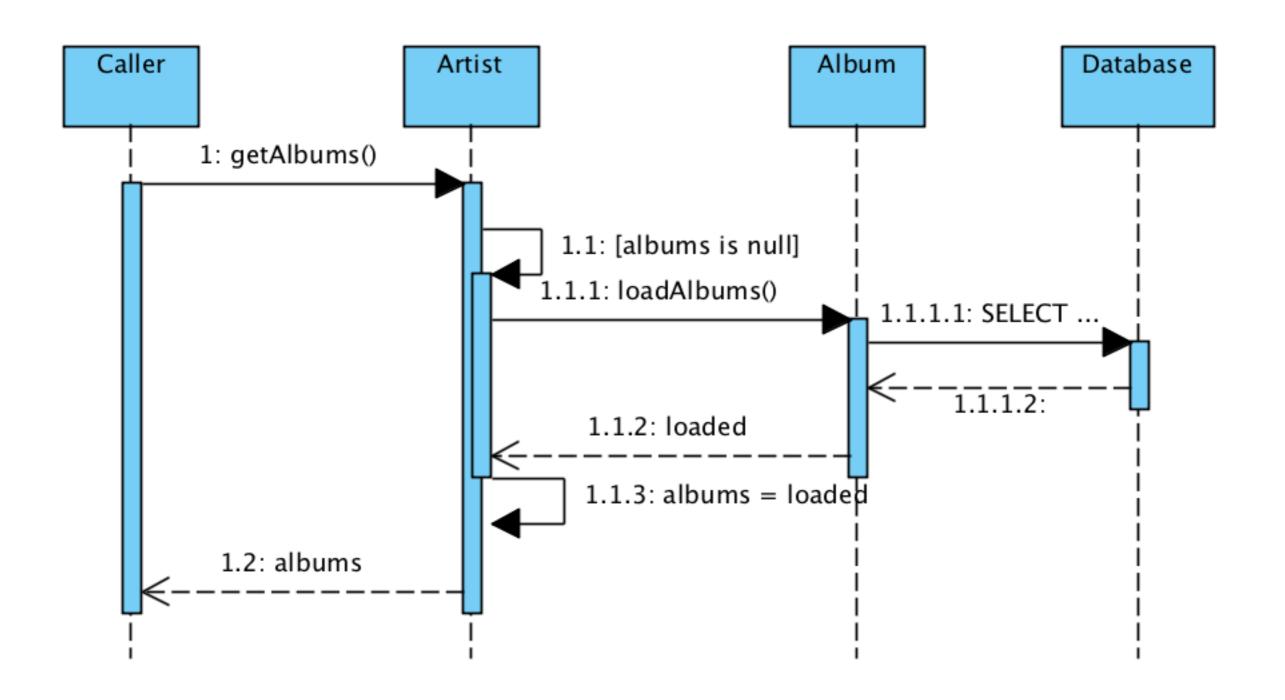

How to accelerate the access to the persistent layer?

Identity Map

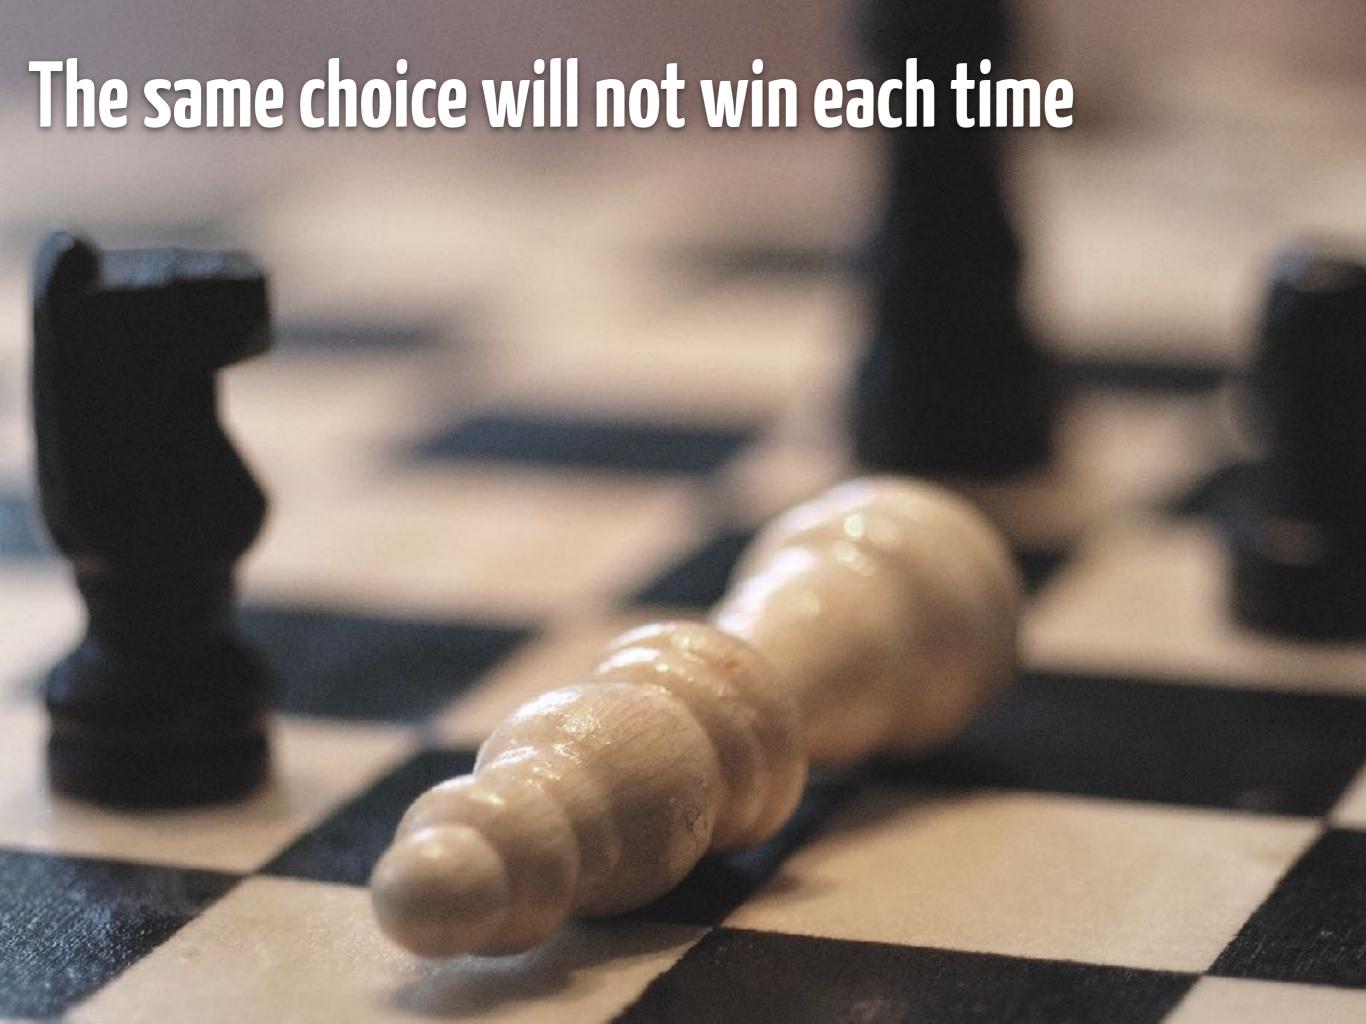

How to ease the burden of data loading?

Lazy Loading

Conclusions

If you only have an hammer, everything looks like a nal
